**P2.** Show (give an example other than the one in **Figure 6.5**) that two-dimensional parity checks can correct and detect a single bit error. Show (give an example of) a double-bit error that can be detected but not corrected.

		Row parity								
	d <sub>1,1</sub>		$d_{1,j}$	$d_{1,j+1}$						
Column parity	d <sub>2,1</sub>		$d_{2,j}$	d <sub>2,j+1</sub>						
	d <sub>i,1</sub>		$d_{i,j}$	$d_{i,j+1}$						
	$d_{i+1,1}$		d <sub>i+1,j</sub>	d <sub>i+1, j+1</sub>						

No errors					si	Correctable single-bit error						
1	0	1	0	1	1	1	0	1	0	1	1	
1	1	1	0	0	0	1	-0	1	1	0	0	→ Parity error
0	1	1	1	0	1	0	1	1	1	0	1	
0	0	1	0	1	0	0	0	1	0	1	0	
	Parity error											

**P5.** Consider the 5-bit generator, G=10011, and suppose that D has the value 1010101010. What is the value of R?

**P8.** In Section 6.3, we provided an outline of the derivation of the efficiency of slotted ALOHA. In this problem we'll complete the derivation.

- a. Recall that when there are N active nodes, the efficiency of slotted ALOHA is Np(1-p)<sup>N-1</sup>. Find the value of p that maximizes this expression.
- b. Using the value of p found in (a), find the efficiency of slotted ALOHA by letting N approach infinity. *Hint*:  $(1-1/N)^N$  approaches 1/e as N approaches infinity.

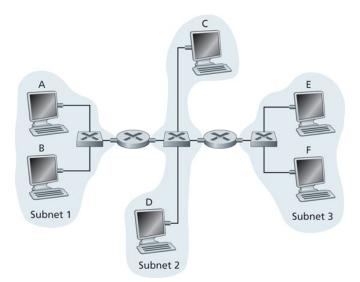

**P11.** Suppose four active nodes—nodes A, B, C and D—are competing for access to a channel using slotted ALOHA. Assume each node has an infinite number of packets to send. Each node attempts to transmit in each slot with probability *p*. The first slot is numbered slot 1, the second slot is numbered slot 2, and so on.

- a. What is the probability that node A succeeds for the first time in slot 4?
- b. What is the probability that some node (either A, B, C or D) succeeds in slot 5?
- c. What is the probability that the first success occurs in slot 4?
- d. What is the efficiency of this four-node system?

**P13.** Consider a broadcast channel with N nodes and a transmission rate of R bps. Suppose the broadcast channel uses polling (with an additional polling node) for multiple access. Suppose the amount of time from when a node completes transmission until the subsequent node is permitted to transmit (that is, the polling delay) is  $d_{poll}$ . Suppose that within a polling round, a given node is allowed to transmit at most Q bits. What is the maximum throughput of the broadcast channel?

**P14.** Consider three LANs interconnected by two routers, as shown in **Figure 6.33**.

- a. Assign IP addresses to all of the interfaces. For Subnet 1 use addresses of the form 192.168.1.xxx; for Subnet 2 uses addresses of the form 192.168.2.xxx; and for Subnet 3 use addresses of the form 192.168.3.xxx.
- b. Assign MAC addresses to all of the adapters.
- c. Consider sending an IP datagram from Host E to Host B. Suppose all of the ARP tables are up to date. Enumerate all the steps, as done for the single-router example in **Section 6.4.1**.
- d. Repeat (c), now assuming that the ARP table in the sending host is empty (and the other tables are up to date).

**P17.** Recall that with the CSMA/CD protocol, the adapter waits  $K \cdot 512$  bit times after a collision, where K is drawn randomly. For K=100, how long does the adapter wait until returning to Step 2 for a 100 Mbps broadcast channel? For a 1 Gbps broadcast channel?

**P18.** Suppose nodes A and B are on the same 10 Mbps broadcast channel, and the propagation delay between the two nodes is 325 bit times. Suppose CSMA/CD and Ethernet packets are used for this broadcast channel. Suppose node A begins transmitting a frame and, before it finishes, node B begins transmitting a frame. Can A finish transmitting before it detects that B has transmitted? Why or why not? If the answer is yes, then A incorrectly believes that its frame was successfully transmitted without a collision. *Hint*: Suppose at time t=0 bits, A begins transmitting a frame. In the worst case, A transmits a minimum-sized frame of 512+64 bit times. So A would finish transmitting the frame at t=512+64 bit times. Thus, the answer is no, if B's signal reaches A before bit time t=512+64 bits. In the worst case, when does B's signal reach A?

**P21.** Consider **Figure 6.33** in **problem P14**. Provide MAC addresses and IP addresses for the interfaces at Host A, both routers, and Host F. Suppose Host A sends a datagram to Host F. Give the source and destination MAC addresses in the frame encapsulating this IP datagram as the frame is transmitted (*i*) from A to the left router, (*iii*) from the left router to the right router, (*iii*) from the right router to F. Also give the source and destination IP addresses in the IP datagram encapsulated within the frame at each of these points in time.
